

NEURO SCIENCE - NEURO-TRANSMITTER TESTING

Medical research has established a definitive link between numerous health conditions and neurotransmitter and endocrine imbalances. The ability to assess the levels of various neurotransmitters and adrenal hormones offers healthcare practitioners a useful tool in addressing neurotransmitter-related conditions such as: anxiety, general malaise, fatigue, adrenal dysfunction, poor concentration, impulsive behavior, muscle problems, mood disorders, depression, restlessness, forgetfulness, insomnia, movement disorders and other neurological dysfunctions.

Emerging evidence links inflammation to atherosclerosis, arterial hypertension, cardiovascular disease and stroke. These tests are useful in the identification of high-risk patients and may help direct further evaluation and therapy in the primary prevention of cardiovascular and coronary artery disease. Stress, toxins, poor diet, chronic inflammation, infections, diseases, the aging process and the environment can all have an effect on the metabolic system. The metabolic system requires balance to maintain homeostasis.

In order to resolve chronic illness, the root cause must be identified and eliminated. NeuroScience, Inc. offers a variety of tests to address the above problems as well as identify immune responses to bacteria, viruses, fungi and metals to determine if they are the root cause of the patient's symptoms. Left untreated, persistent infections and inflammation can result in exacerbations of symptoms including pain, cognitive impairment psychiatric effects and organ damage.
