

What Parents should know about Attention Deficit Disorder With or Without Hyperactivity (ADD/H)

Depression, Anxiety, Emotional and Cognitive functioning

Attention deficit Disorder with or without hyperactivity disorder (ADD/H) is one of the most common childhood disorders and can continue through adolescence and adulthood, which also has been commonly ignored. Minimal brain dysfunctions, or abnormal cerebral structures, and/or brain's chemical imbalance affect people so that they may experience periods of explosive rage that can lead to violent episodes, and thus violent crimes. These dysfunctions of the brain are typically diagnosed as attention deficit disorders with or without hyperactivity (ADHD), which is another suspected cause of antisocial behavior, conduct disorder, substance abuse, crime, and delinquency (Pratt, Cullen, Blevins, Daigle, & Unnever, 2002). Furthermore, ADHD is associated with a variety of conditions that are risk factors for offending, including neuropsychological deficits, poor academic and cognitive skills, truancy, psychological problems, and defiance and aggression.

Lack of Attention, Concentration, Antisocial Behavior, and Substance Abuse

Do you See the above Symptoms and Behaviors in your Teens?
Get to the Source and Take a closer Look at your child's Symptoms and Behaviors

A Comprehensive Assessment Evaluation and Diagnosis including our exceptional integrated Neurocognitive Approach "Visual Concentration Attention Therapy (VCAT)" combined with Neurofeedback (EEG), and in real time Brain Mapping in targeting and treating the underlying cause of ADD/H
